Opinion

The New Universe

MEMPHIS, SUNDAY OCTOBER 23, 2022

WHAT DO EXPENSIVE NEW TELESCOPES DO FOR HUMANITY TODAY?

Are mega-projects like ALMA, LIGO, JWST, and Gaia worth the billions?

ARE COMPUTERS THE NEW TELESCOPES?

New galaxies in-silico, the early Universe without physics, and new stars forming in your hand.

IS ASTROPHYSICS BEING (RE)ORGANIZED?

Lone stargazers are a rarer and rarer breed in professional astronomy. Teams and data scientists seem the way of the future, and tools that talk to each other are essential.

Women at the Harvard College Observatory

Williamina Fleming shown standing right of center. Harvard University Archives

Williamina Fleming

Discovered Horsehead Nebula in 1888 and the first white dwarf in 1910. She became the first woman with an officially appointed job at Harvard as Curator of Astronomical Photographs in 1898.

Antonia Maury

First to detect and calculate the orbit of a spectroscopic binary, which was published in 1933. She worked intermittently with Harvard College Observatory before returning in 1918 as an adjunct professor until her retirement in 1948.

Henrietta Swan Leavitt

Found period-luminosity relation for Cepheid variable stars in 1912, providing astronomers with the first "standard candle" with which to measure the distance to faraway galaxies.

Annie Jump Cannon

Developed the Harvard Classification Scheme in 1922, the stellar classification system still in use today. In 1938, two years before retirement, she finally obtained a regular appointment from Harvard as William C. Bond Astronomer.

Cecilia Payne-Gaposchkin

Determined the chemical composition of stars, particularly that hydrogen and helium are the most abundant elements. She was the first person awarded a PhD in Astronomy at Harvard, and in 1956 she became Harvard's first regularly appointed female professor and the first female department chair.

How do stars form?

Phenomenon

Observation

Data

Rule

Theory

Explanation

Prediction

Phenomenon

Looks like there are stars and clouds of darkness in the Sky.

Observation

Let's *observe* them every way we know how.

Data

And *keep track* of everything we find.

Rule

Bright nebulae are often *near* dark cloudy patches.

Theory

Stars *form* from *collapsing* gas in the clouds.

Explanation

Bright nebulae are *caused* by new stars lighting up clouds.

Prediction

Dark clouds form new stars, *even if we can't see them*.

The New Universe

MEMPHIS, SUNDAY OCTOBER 23, 2022

ARE COMPUTERS THE NEW TELESCOPES?

New galaxies in-silico, the early Universe without physics, and new stars forming in your hand.

OUT THERE | DENNIS OVERBYE

Where Our Bubble Ends, Our Understanding Begins

By mapping a region devoid of gas and dust, scientists learn more about star formation.

JUST A BIT TOO LATE for New Year celebrations, astronomers have discovered that the Milky Way galaxy, our home, is, like champagne, full of bubbles. As it happens, our solar system is passing through the center of one of these bubbles. Fourteen million years ago, according to the astronomers, a firecracker chain of supernova explosions drove off all the gas and dust from a region roughly 1,000 light-years wide, leaving it bereft of the material needed to produce new generations of stars. As a result, all the baby stars in our neighborhood can be found stuck on the edges of this bubble. There, the staccato force of a previous generation of exploding stars has pushed gas clouds together into forms dense enough to collapse under their own ponderous diffuse gravity and condense enough to ignite, as baby stars. Our sun, 4.5 billion years old, drifts through the middle of this space in a coterie of aged stars.

NYT, January 25, 2022

Last year, a group of scientists led by João Alves, an astrophysicist at the University of Vienna announced the discovery of the Radcliffe Wave, an undulating string of dust and gas clouds 9,000 light-years long that might be the spine of our local arm of the galaxy. One section of the wave now appears to be part of our Local Bubble.

Above, an illustration of the Local Bubble, which formed in the Milky Way, left, when supernova explosions drove off all the gas and dust from a 1,000-light-year-wide region. Local Bubble began 14 million years ago with a massive supernova, the first of about 15, massive stars died and blew up. Their blast waves cleared out the region. There are now no stars younger than 14 million years in the bubble, Dr. Goodman said. The bubble continues to grow at about 4 miles a second. "Still, more supernovae are expected to take place in the near future, like Antares, a red supergiant star near the edge of the bubble that could go supernova now," Dr. Alves said. "So the Local Bubble is not 'done.' With a score of well-known star-forming regions sitting on the surface of the bubble, the next generation of stars is securely on tap.

The team plans to go on and map more bubbles in the our Milky Way fluff of champagne. There must be more, Dr. Goodman said, because it would be too much of a coincidence for the sun to be smack in the middle of the only one. The sun's presence in this one is nonetheless coincidental, Dr. Alves said. Our star wandered into the region only five million years ago — long after most of the action — and will exit about five million years from now. The motions of the stars are more irregular than commonly portrayed, as they are bumped gravitationally by other stars, clouds and the like, Dr. Alves said. "The sun is moving at a significantly different velocity than the average of the stars and gas in the solar neighborhood," he noted. This would enable it to catch up and pass — or be passed by — the bubble. "It was a revelation," Dr. Goodman said, "how kooky the sun's path really is compared with a simple circle."

EARLIER TODAY...

THE SCIENCE STORY

Several recent journal articles and data explorations by the scientists in our collaboration have motivated this project. The articles used a wide variety of data types and techniques to uncover several new 3D structures—some whose motions are also measured—in the Sun’s neighborhood of the Milky Way, including [The Radcliffe Wave](#), [The Perseus-Taurus Supershell](#), the arrangement of star-forming regions on the surface of [The Local Bubble](#) around the Sun, new [cavities created by star formation near the Orion nebula](#), and new compilations of young stars’ properties, motions and positions. The combination of data and visualization from these and several related projects will be summarized in a ~2023 article entitled the “Charting the Nearby Milky Way in 3D,” aimed at a “Scientific American” level audience. Data and interactive visualizations included in that initial article from our collaboration will be offered and archived publicly online, using the MAST, Dataverse, and milkyway3d.org mechanisms described in “The Data Story” above.

The Radcliffe Wave

The Radcliffe Wave is a gigantic structure that defines the shape of the Sun’s local neighborhood in the Milky Way Galaxy. Its existence was first presented officially in a paper published in *Nature* on January 7, 2020. [Its website](#) offers scientists, educators, and the interested public much more information about the “RadWave,” as we like to call it. Please use this page to find publications and talks, visuals (images, interactives, and videos), history, team info, software,

The Perseus-Taurus Supershell

Astronomers analyzing 3D maps of the shapes and sizes of nearby molecular clouds have discovered a [gigantic cavity in space](#). The sphere-shaped void, described in the *Astrophysical Journal Letters*, spans about 150 parsecs — nearly 500 light years — and is located on the sky among the constellations Perseus and Taurus. The research team believes the cavity was formed by ancient supernovae that went off some 10 million

The Local Bubble

The discovery that the 1000-light-year-wide “Local Bubble” surrounding the Sun and Earth is responsible for the formation of all nearby, young stars was first presented in a paper published in *Nature* on January 12, 2022. Please use this [page](#) to find **news, publications and talks, visuals**(images, interactives, and videos), **team info, and data**.

Edited by Neta A. Bahcall, Princeton University, Princeton, NJ, and approved March 11, 2021 (received for review October 26, 2020)

May 4, 2021 | 118 (19) e2022038118 | <https://doi.org/10.1073/pnas.2022038118>

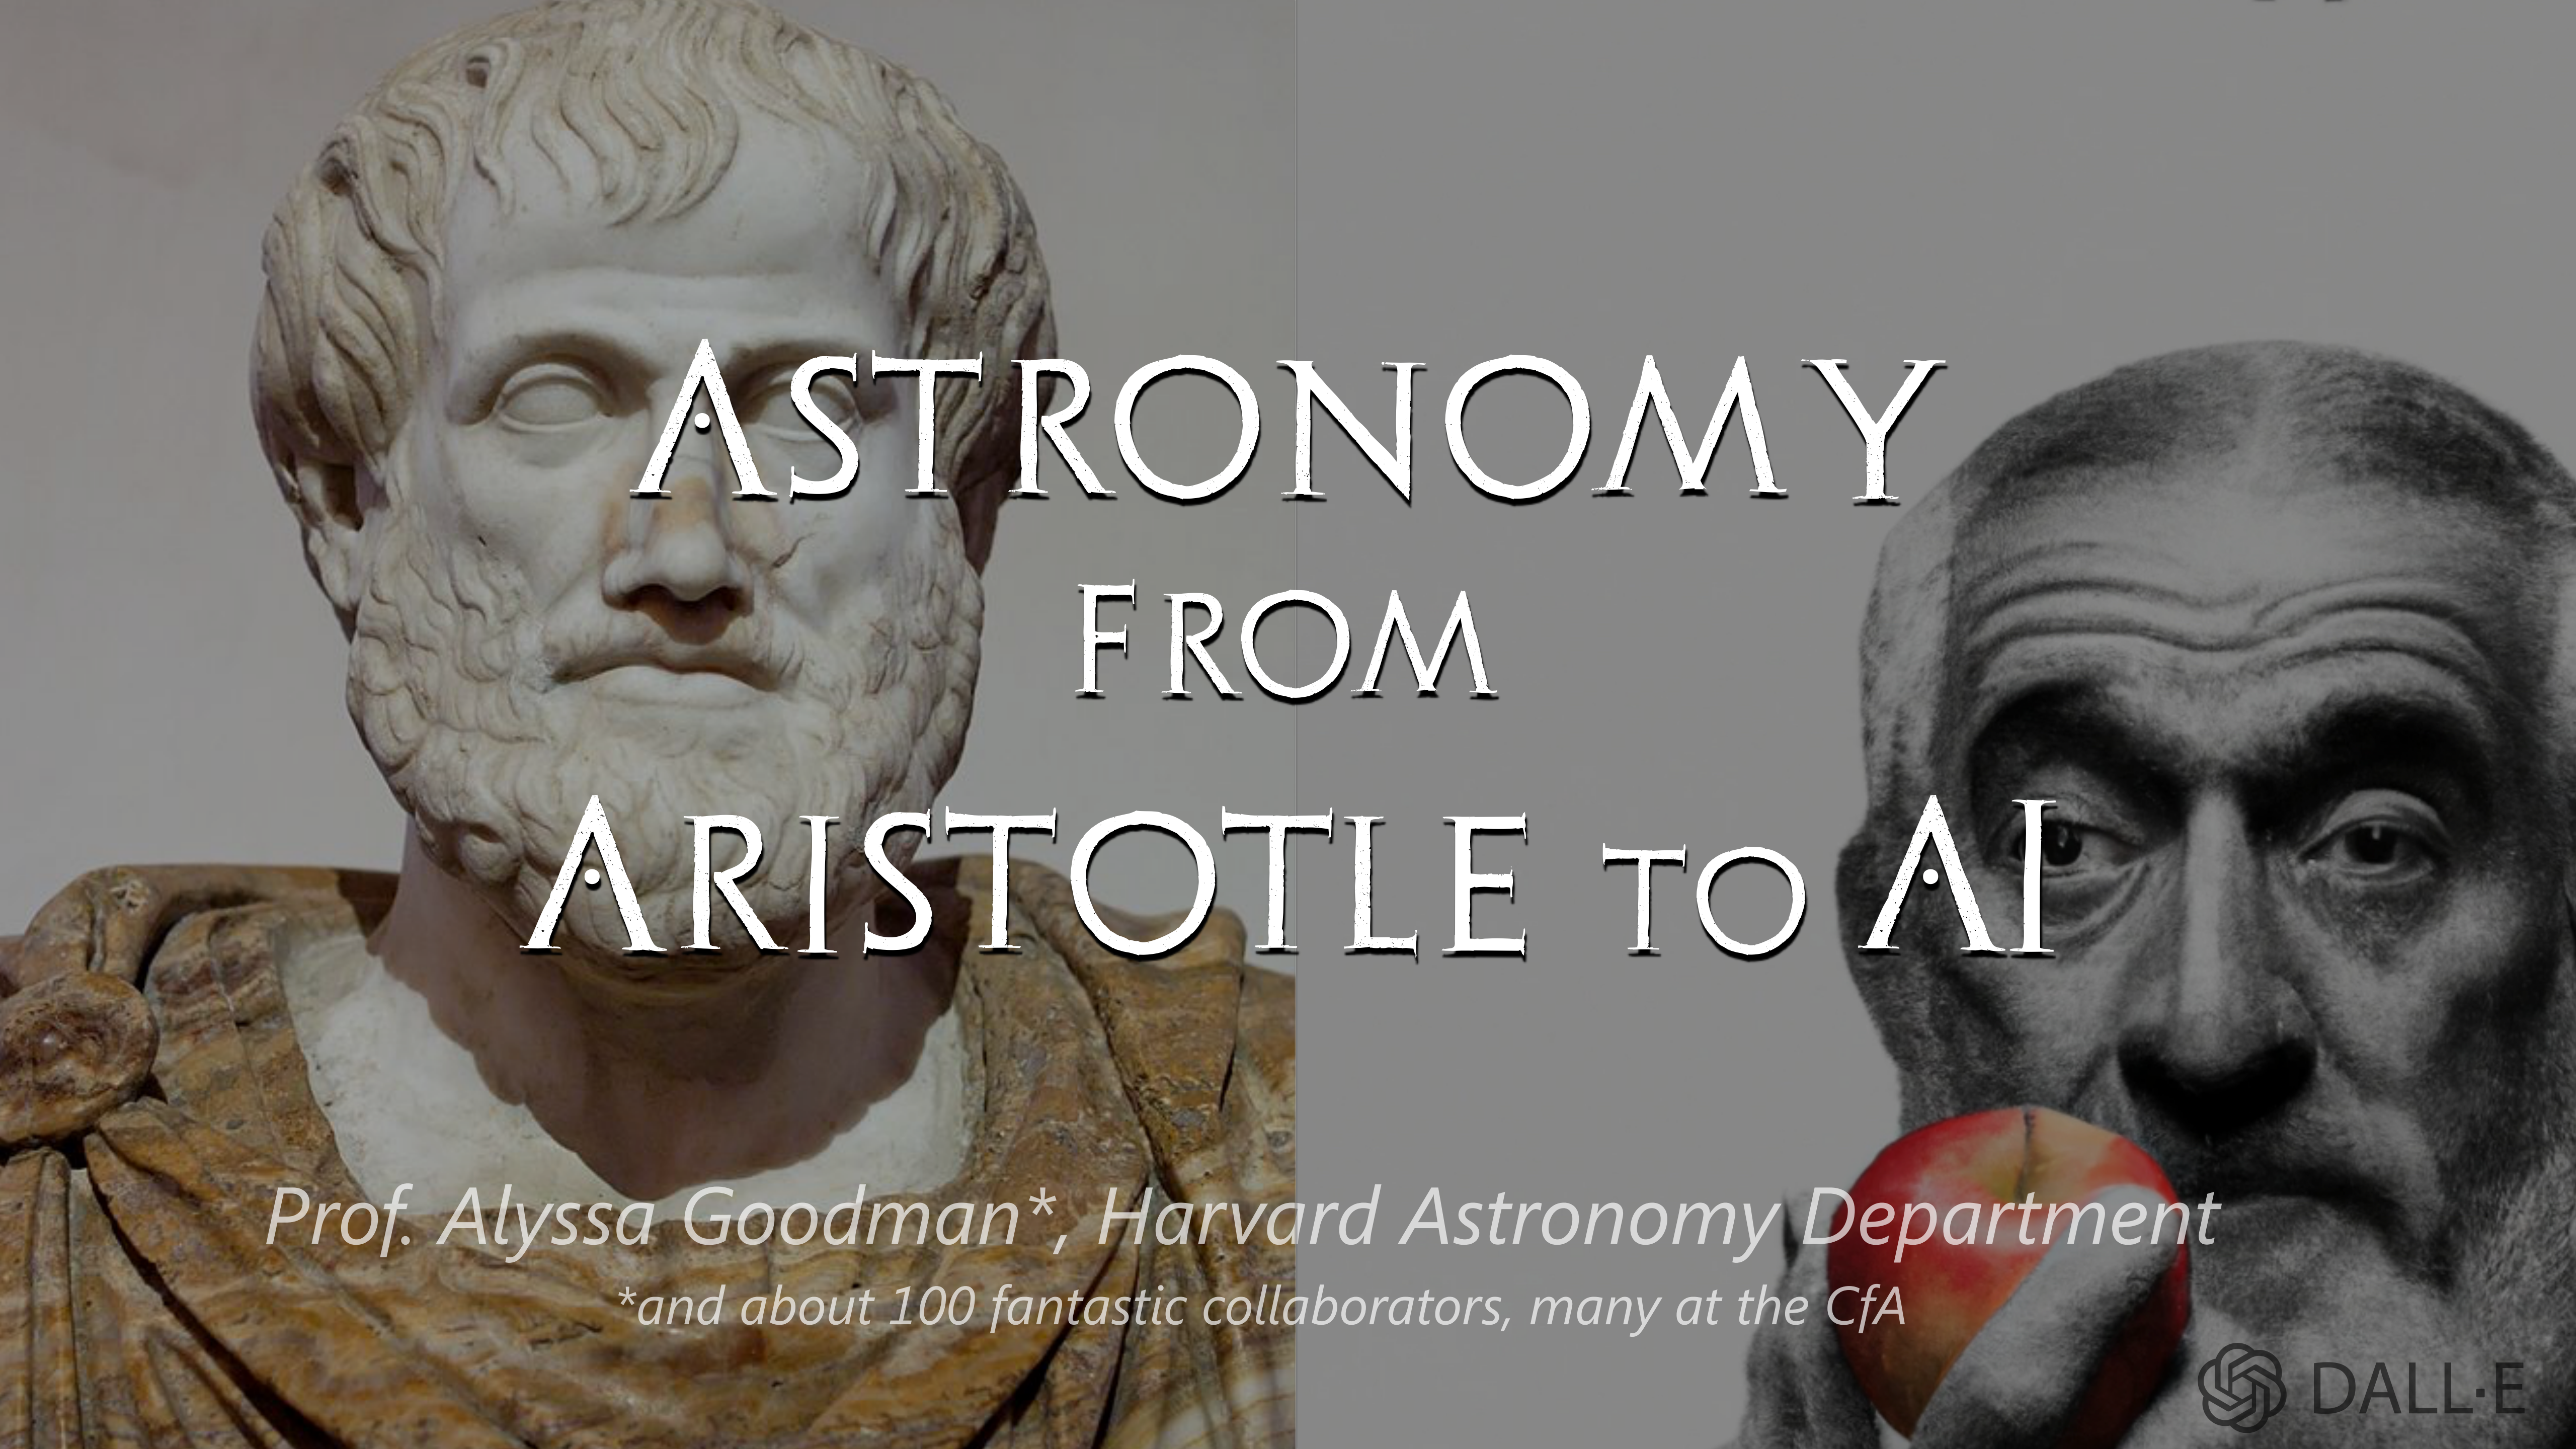

Significance

Cosmological simulations are indispensable for understanding our Universe, from the creation of the cosmic web to the formation of galaxies and their central black holes. This vast dynamic range incurs large computational costs, demanding sacrifice of either resolution or size and often both. We build a deep neural network to enhance low-resolution dark-matter simulations, generating superresolution realizations that agree remarkably well with authentic high-resolution counterparts on their statistical properties and are orders-of-magnitude faster. It readily applies to larger volumes and generalizes to rare objects not present in the training data. Our study shows that deep learning and cosmological simulations can be a powerful combination to model the structure formation of our Universe over its full dynamic range.
